escape-sequence

```

\section*{Usage}

Usage of escape sequences in string literal and string lengths is given elsewhere (see Table 866.2 and Figure 293.1).

In translation phase 6, the multibyte character sequences specified by any sequence of adjacent character and wide string literal tokens are concatenated into a single multibyte character sequence.

\section*{Usage}

In the visible form of the .c files \(4.9 \%\) (.h \(15.6 \%\) ) of all string literals are concatenated (i.e., immediately adjacent to another string literal) and \(1.4 \%\) (.h \(10.7 \%\) ) occupied more than one source line (i.e., line splicing occurred).

The value of a string literal containing a multibyte character or escape sequence not represented in the execution character set is implementation-defined.

\section*{Usage}

In the visible form of the .c files \(2.1 \%\) (.h \(2.9 \%\) ) of characters in string literals are not in the basic execution character set (the value of escape sequences were compared using the values of the Ascii character set).
string literal distinct array

It is unspecified whether these arrays are distinct provided their elements have the appropriate values.
Table 908.1: Number of string-literals (the empty string-literal, i.e., "", was not counted). Based on the visible form of the .c and .h files. Although many of the program source trees contain more than one program, they were treated as a single entity. A consequence of this is that the number of unique matches represents a lower bound; having a smaller number of string literals is likely to reduce the probability of matches occurring.
\begin{tabular}{lrrrrrrrr}
\hline & gcc & idsoftware & linux & netscape & openafs & openMotif & postgresql & Total \\
\hline Number of strings & 38,063 & 21,811 & 177,224 & 30,358 & 30,574 & 11,285 & 16,387 & 325,702 \\

\section*{Usage}

While over \(30 \%\) of the characters in this book's benchmark programs (see Table 770.3) are contained within comments, they only represent around \(2 \%\) of the tokens. A study by Fluri et al \({ }^{[68]}\) of the releases of three large Java programs over a 6 year period (on average) found three different patterns in the ratio of number of comment lines to number of non-comment lines for each program.
A study of comments in \(\mathrm{C}++\) source by Etzkorn \({ }^{[65]}\) found that \(57 \%\) contained English sentences (that could be automatically parsed by the tool used).

Table 933.1: Common formats of nonsentence style comments. Adapted from Etzkorn, Bowen, and Davis. \({ }^{[65]}\)
\begin{tabular}{ll}
\hline Style of Comment & Example \\
\hline Item name- Definition & MaxLength- Maximum CFG Depth. \\

\section*{Usage}
partial redundancy elimination

A study by Bodík, Gupta, and Soffa \({ }^{[19]}\) found that \(13.9 \%\) of the expressions in SPEC95 were partially redundant, that is, their evaluation is not necessary under some conditions.

See Table 1713.1 for information on occurrences of full expressions, and Table 770.2 for visual spacing between binary operators and their operands.

Table 940.2: Occurrence of a token as the first token on a physical line (as a percentage of all occurrences of that token and as a percentage of all lines). /* new-line */ denotes a comment containing one or more new-line characters, while /*... */ denotes that form of comment on a single line. Based on the visible form of the .c files.
\begin{tabular}{|c|c|c|c|c|c|}

Figure 943.1: English ("Chris is talking with Pat") and Japanese ("John-ga Mary to renaisite irue") language phrase structure for sentences of similar complexity and structure. While the Japanese structure may seem back-to-front to English speakers, it appears perfectly natural to native speakers of Japanese. Adapted from Baker. \({ }^{[13]}\)

Figure 944.1: A simplified form of the kind of tree structure that is likely to be built by a translator for the expression \(a[i]=x *(y+z)\).

Table 940.4: Number of objects defined (in a variety of small multimedia and scientific programs) to have types represented using a given number of bits (i.e., mostly 32 -bit int) and number of objects having a maximum bit-width usage (i.e., number of bits required to represent any of the values stored in the object; rounded up to the nearest byte boundary). Adapted from Stephenson, \({ }^{[156]}\) whose analysis was performed by static analysis of the source.
\begin{tabular}{rrc}
\hline Bits & Objects Defined & Objects Requiring Specified Bits \\
\hline 1 & 0 & 203 \\
8 & 7 & 134 \\
16 & 27 & 108 \\
32 & 686 & 275 \\
\hline
\end{tabular} expression order of evaluation

The grouping of operators and operands is indicated by the syntax. \({ }^{72)}\)

Except as specified later (for the function-call (), \&\&, II, ?:, and comma operators), the order of evaluation of subexpressions and the order in which side effects take place are both unspecified.

An identifier is a primary expression, provided it has been declared as designating an object (in which case it 976 is an Ivalue) or a function (in which case it is a function designator). \({ }^{77)}\)

\section*{Usage}

A study by Yang and Gupta \({ }^{[174]}\) found, for the SPEC95 programs, on average eight different values occupied \(48 \%\) of all allocated storage locations throughout the execution of the programs. They called this behavior frequent value locality. The eight different values varied between programs and contained small values (zero was often the most frequently occurring value) and very large values (often program-specific addresses of objects and string literals).

Table 976.1: Dynamic percentage of load instructions from different classes. The Class column is a three-letter acronym: the first letter represents the region of storage (Stack, Heap, or Global), the second denotes the kind of reference (Array, Member, or Scalar), and the third indicates the type of the reference (Pointer or Nonpointer). For instance, \(H F P\) is a load of pointer-typed member from a heap-allocated object. There are two kinds of loads generated as a result of internal translator housekeeping: \(R A\) is a load of the return address from a function-call, and any register values saved to memory prior to the call also need to be reloaded when the call returns, \(C S\) callee-saved registers The figures were obtained by instrumenting the source prior to translation. As such they provide a count of loads that would be made by the abstract machine (apart from \(R A\) and \(C S\) ). The number of loads performed by the machine code generated by translators is likely to be optimized (evaluation of constructs moved out of loops and register contents reused) and resulting in fewer loads. Whether these optimizations will change the distribution of loads in different classes is not known. Adapted from Burtscher, Diwan and Hauswirth. \({ }^{[24]}\)

array row-major storage order

It follows from this that arrays are stored in row-major order (last subscript varies fastest).

Figure 994.1: Row (left) and column (right) major order. The dotted line indicates successively increasing addresses for the two kinds of storage layouts, with the gray boxes denoting the same sequence of index values.
\[

\]

Figure 994.2: Difference in storage layout between an array of array of characters (left) and array of pointer to characters (right; not all pointers shown and the relative storage locations of the strings is only one of many that are possible).

Table 994.1: Cache hit-rate for sequentially accessing, in row-major order, a two-dimensional array stored using various layout methods. If the same array is accessed in column-major order the figures given in the Row-major and Column-major columns are swapped and the Morton layout figure remains unchanged. These figures ignore the impact that accessing other objects might have on cache behavior, and so denote the best hit-rate that can be achieved. Based on Thiyagalingam et al. \({ }^{[164]}\)
\begin{tabular}{llll}
\hline Cache size & Row-major & Morton & Column-major \\
\hline 32 byte cache line & \(75 \%\) & \(50 \%\) & \(0 \%\) \\
128 cache byte & \(93.75 \%\) & \(75 \%\) & \(0 \%\) \\
8K byte cache page & \(99.9 \%\) & \(96.875 \%\) & \(0 \%\) \\
\hline
\end{tabular}

1000 A postfix expression followed by parentheses () containing a possibly empty, comma-separated list of expressions is a function call.

\section*{Usage}

How frequent are function calls? The machine code instructions used to call a function may be generated by translators for reasons other than a function call in the source code. Some operators may be implemented via a call to an internal system library routine; for instance, floating-point operations on processors that do not support such operators in hardware. Such usage will vary between processors (see Figure 0.5).

Figure 994.3: Two possible element layouts of an \(8 * 8\) array; Blocked row-major layout (left) and Morton element layout (right). Factors such as efficiency of array index calculation, whether array size can be made a power of two, or array shape (e.g., non-square) drive layout selection. \({ }^{[163]}\)

\hline
\end{tabular}

1002 The list of expressions specifies the arguments to the function.

\section*{Usage}

Usage information on the number of arguments in calls to functions is given elsewhere.

289 function call number of arguments

\section*{1003 An argument may be an expression of any object type.}

\section*{Usage}

Information on parameter types is given elsewhere (see Table 1831.1).
Table 1003.1: Occurrence of various argument types in calls to functions (as a percentage of argument types in all calls). Based on the translated form of this book's benchmark programs.
\begin{tabular}{lrlr}
\hline Type & \(\%\) & Type & \(\%\) \\
\hline struct * & 26.8 & void \(*\) & 4.0 \\
int & 16.5 & union \(*\) & 3.4 \\
const char * & 9.7 & unsigned char & 2.5 \\
char * & 8.4 & enum & 2.1 \\
other-types & 8.0 & unsigned short & 1.9 \\
unsigned int & 7.1 & const void * & 1.8 \\
unsigned long & 6.3 & long & 1.4 \\
\hline
\end{tabular}

1004 In preparing for the call to a function, the arguments are evaluated, and each parameter is assigned the value of the corresponding argument. \({ }^{79)}\)

Figure 1004.1: A processor's register file (on the left) and a mapping to register windows for registers accessible to a program, after \(0,1,2\), and 3 call instructions have been executed. The mapping of the first eight registers is not affected by the call instruction.

\section*{If the expression that denotes the called function has type pointer to function returning an object type, the function call expression has the same type as that object type, and has the value determined as specified in 6.8.6.4. \\ Table 1005.1: Occurrence of various return types in calls to functions (as a percentage of the return types of all function calls). Based on the translated form of this book's benchmark programs.}
\begin{tabular}{lrlr}
\hline Type & \(\%\) & Type & \(\%\) \\
\hline void & 35.8 & union \(*\) & 3.2 \\
int & 30.5 & unsigned long & 3.1 \\
struct * & 9.1 & char * & 3.1 \\
void * & 6.3 & unsigned int & 2.1 \\
other-types & 5.2 & char & 1.6 \\
\hline
\end{tabular}

\section*{Usage}

In most programs an identifier is converted in more than \(99 \%\) of cases, although a lower percentage is occasionally seen (see Table 1001.1).

On the other hand, it is possible to pass a pointer to an object, and the function may change the value of the object pointed to.
function definition ends with ellipsis

If the function is defined with a type that includes a prototype, and either the prototype ends with an ellipsis (, \(\ldots\). ) or the types of the arguments after promotion are not compatible with the types of the parameters, the behavior is undefined.
78) Most often, this is the result of converting an identifier that is a function designator.

Figure 1011.1: An example of the impact, on relative stack addresses, of passing an argument having a type that occupies more storage than the declared parameter type. For instance, the offset of \(z\), relative to the frame pointer \(f p\), might be changed by passing an argument having a type different from the declared type of the parameter \(y\) (this can occur when there is no visible prototype at the point of call to cause the type of the argument to be converted).

\section*{Usage}

Pointer types are the most commonly occurring kind of parameter type (see Table 1831.1).

1031 A postfix expression followed by the . operator and an identifier designates a member of a structure or union object.

Table 1031.1: Number of member selection operators of the same object (number of dot selections is indicated down the left, and the number of indirect selections across the top). For instance, x.m1->m2 is counted as one occurrence of the dot selection operator with one instance of the indirect selection operator. Based on the translated form of this book's benchmark programs.
\begin{tabular}{lrrrrrr}
\hline\(. \backslash->\) & 0 & 1 & 2 & 3 & 4 & 5 \\
\hline 0 & 0 & 165,745 & 10,396 & 522 & 36 & 4 \\
1 & 28,160 & 34,065 & 3,437 & 230 & 7 & 0 \\
2 & 3,252 & 6,643 & 579 & 26 & 0 & 0 \\
3 & 363 & 309 & 35 & 5 & 0 & 0 \\
4 & 16 & 33 & 2 & 0 & 0 & 0 \\
5 & 0 & 15 & 0 & 0 & 0 & 0 \\
\hline
\end{tabular}

1037 One special guarantee is made in order to simplify the use of unions: if a union contains several structures that share a common initial sequence (see below), and if the union object currently contains one of these structures, it is permitted to inspect the common initial part of any of them anywhere that a declaration of the complete type of the union is visible.

\section*{Usage}

Measurements by Stiff et al. \({ }^{[159]}\) of 1.36 MLOC (the SPEC 95 benchmarks, gcc, binutils, production code from a Lucent Technologies' product and a few other programs) showed a total of 23,947 casts involving 2,020 unique types. For the void \(* \Leftrightarrow\) struct \(*\) conversion, they found 2,753 upcasts ( 610 unique types), 2,788 downcasts ( 606 unique types), and 538 cases ( 60 unique types) where there was no matching between the associated up/down casts. For the struct \(* \Leftrightarrow\) struct \(*\) conversions, they found 688 upcasts (78 unique types), 514 downcasts ( 66 unique types), and 515 cases ( 67 unique types) where there was no relationship associated with the types.

1053 Forward references: additive operators (6.5.6), compound assignment (6.5.16.2).
Usage
No usage information is provided on compound literals because very little existing source code contains any use of them.

EXAMPLE string literals shared

EXAMPLE 6 Like string literals, const-qualified compound literals can be placed into read-only memory and 1076 can even be shared. For example,
```

(const char []){"abc"} == "abc"

```
might yield 1 if the literals' storage is shared.

\section*{Usage}

In the visible source of the .c files \(0.1 \%\) of string literals appeared as the operand of the equality operator (representing \(0.3 \%\) of the occurrences of this operator).

\end{tabular}

1095 The unary * operator denotes indirection.

\section*{Usage}

A study by Mock, Das, Chambers, and Eggers \({ }^{[124]}\) looked at how many different objects the same pointer dereference referred to during program execution (10 programs from the SPEC95 and SPEC2000 benchmarks were used). They found that in \(90 \%\) to \(100 \%\) of cases (average \(98 \%\) ) the set of objects pointed at, by a particular pointer dereference, contained one item. They also performed a static analysis of the source using a variety of algorithms for deducing points-to sets. On average (geometric mean) the static points to sets were 3.3 larger than the dynamic points to sets.

Table 1103.1: Occurrence of the unary! operator in various contexts (as a percentage of all occurrences of this operator and the percentage of all occurrences of the given context that contains this operator). Based on the visible form of the .c files.
\begin{tabular}{lrr}
\hline Context & \% of ! & \% of Contexts \\
\hline if control-expression & 91.0 & 17.4 \\
while control-expression & 2.3 & 8.2 \\
for control-expression & 0.3 & 0.7 \\
switch control-expression & 0.0 & 0.0 \\
other contexts & 6.4 & - \\
\hline
\end{tabular}

The expression ! E is equivalent to ( \(\mathbf{0}=\mathbf{=} \mathrm{E}\) ).

\section*{Usage}

The visible form of the .c files contain 95,024 instances of the operator ! (see Table 912.2 for information on punctuation frequencies) and 27,008 instances of the token sequence \(==0\) (plus 309 instances of the form \(==0 \times 0\) ). Integer constants appearing as the operand of a binary operator occur 28 times more often as the right operand than as the left operand.

The sizeof operator shall not be applied to an expression that has function type or an incomplete type, to the parenthesized name of such a type, or to an expression that designates a bit-field member.

Table 1118.1: Occurrence of the sizeof operator having particular operand types (as a percentage of all occurrences of this operator). Based on the translated form of this book's benchmark programs.
\begin{tabular}{lrlr}
\hline Type & \(\%\) & Type & \(\%\) \\

\hline
\end{tabular}
cast-expression:
unary-expression
( type-name ) cast-expression

\section*{Usage}

Measurements by Stiff, Chandra, Ball, Kunchithapadam, and Reps \({ }^{[159]}\) of 1.36 MLOC (SPEC95 version of gcc, binutils, production code from a Lucent Technologies product and a few other programs) showed a total of 23,947 casts involving 2,020 unique types. Of these 15,704 involved scalar types (not involving a structure, union, or function pointer) and 447 function pointer types. Of the remaining casts 7,796 ( 1,276 unique types) involved conversions between pointers to void/char and pointers to structure (in either direction) and 1,053 (209 unique types) conversions between pointers to structs.

\footnotetext{
Unless the type name specifies a void type, the type name shall specify qualified or unqualified scalar type
} and the operand shall have scalar type.

\section*{Usage}

Usage information on implicit conversions is given elsewhere (see Table 653.1).
Table 1134.1: Occurrence of the cast operator having particular operand types (as a percentage of all occurrences of this operator). Based on the translated form of this book's benchmark programs.

\end{tabular}

1147 The result of the binary * operator is the product of the operands.
binary * result

\section*{Usage}

Measurements by Citron, Feitelson, and Rudolph \({ }^{[39]}\) found that in a high percentage of cases the operands of multiplication operations repeat themselves ( \(59 \%\) for integer operands and \(43 \%\) for floating-point). Measurements were based on maintaining previous results in a 32-entry, 4-way associative, cache.

1148 The result of the / operator is the quotient from the division of the first operand by the second;

\section*{Usage}

Measurements by Oberman \({ }^{[131]}\) found that in a high percentage of cases division operations on floating-point operands repeat themselves (i.e., the same numerator and denominator values). The measurements were done using the SPECfp92 and NAS (Fortran-based) benchmarks. \({ }^{[12]}\) Simulations using an infinite division operand cache found a hit rate (i.e., cache lookup could return the result of the division) of \(69.8 \%\), while a cache containing 128 entries had a hit rate of \(60.9 \%\). A more detailed analysis by Citron, Feitelson, and Rudolph \({ }^{[39]}\) found a great deal of variability over different applications, with multimedia applications having hit rates of \(50 \%\) (using a 32 entry, 4 -way associative cache).

An assignment operator stores a value in the object designated by the left operand.

\section*{Usage}
value locality
A study by Lepak, Bell, and Lipasti \({ }^{[110]}\) investigated value locality with respect to store operations (using the SPEC95 benchmarks). They defined a silent store to be a store operation that does not change the system state (i.e., the value being written matches the value already held at the location being stored to). They also defined program structure store value locality (PSSVL) to refer to the same value being stored from the same program location and message-passing store value locality (MPSVL) to refer to the same value being stored to the same address in storage (which may be holding different objects at different times during the execution of a program).

Table 1290.1: Percentage of stores that are silent. The results from two instruction sets, the PowerPC (PPC) and SimpleScalar (SS), are given for silent stores. The measurements for Program Structure Store Value Locality (PSSVL) and Message-Passing Store Value Locality (MPSVL) are for the PowerPC only. Adapted from Lepak, Bell, and Lipasti. \({ }^{[110]}\)

register storage-class

A declaration of an identifier for an object with storage-class specifier register suggests that access to the 1369 object be as fast as possible.

Table 1369.1: Degree of use of floating-point and integer register instances (a particular value loaded into a register). Values denote the percentage of register instances with a particular degree of use (listed across the top), for the program listed on the left. For instance, \(15.51 \%\) of the integer values loaded into a register, in gcc, are used twice. Left half of table refers to floating-point register instances, right half of table to integer register instances. Zero uses of a value loaded into a register occur in situations such as an argument passed to a function that is never accessed. Adapted from Franklin and Sohi. \({ }^{[70]}\)

\begin{array}{l}
\text { const } \\
\text { restrict } \\
\text { volatile }
\end{array}
\end{array}
\end{aligned}
\]

\section*{Usage}

Developers do not always make full use of the const qualifier. An automated analysis \({ }^{[69]}\) of programs whose declarations contained a relatively high percentage ( \(29 \%\) ) of const qualifiers found that it would have been possible to declare \(70 \%\) of the declarations using this qualifier. Engblom \({ }^{[60]}\) reported that for real-time embedded C code \(17 \%\) of object declarations contained the const type qualifier.

Figure 1472.1: Number of files containing a given number of references to each tag previously defined in the visible source of that file (times, bullet, square; the definition itself is not included in the count), tags with no definition visible in the .c file (triangle; i.e., it is defined in a header) and anonymous structure/union/enumeration definitions (star). Based on the visible form of the .c files.

> labeled-statement compound-statement expression-statement selection-statement iteration-statement jump-statement

\section*{Usage}

Of the approximately \(2,204,000\) statements in the visible form of the .c files \(60.3 \%\) were expression-statements, \(21.3 \%\) selection-statements, \(15.0 \%\) jump-statements, and \(3.4 \%\) iteration-statements. Of these \(5.4 \%\) were labeled-statements.

A block allows a set of declarations and statements to be grouped into one syntactic unit.

Figure 1652.1: Number of object declarations that include an initializer (as a percentage of all corresponding object declarations), either within function definitions (functions that did not contain any object definitions were not included), or within translation units and having internal linkage (while there are a number of ways of counting objects with external linkage, none seemed appropriate and no usage information is given here). Based on the translated form of this book's benchmark programs.

Figure 1707.1: Subject confidence level for having previously seen a sentence containing different numbers of idea units. Based on Bransford and Franks. \({ }^{[21]}\)

Romulus, the legendary founder of Rome, took the women of the Sabine by force.
1 (took, Romulus, women, by force)
2 (found, Romulus, Rome)
3 (legendary, Romulus)
4 (Sabine, women)

Cleopatra's downfall lay in her foolish trust in the fickle political figures of the Roman world.
1 (because, \(\alpha, \beta\) )
\(2 \alpha \rightarrow\) (fell down, Cleopatra)
\(3 \beta \rightarrow\) (trust, Cleopatra, figures)
4 (foolish, trust)
5 (fickle, figures)
6 (political, figures)
7 (part of, figures, world)

8 (Roman, world)
Figure 1707.2: Two sentences, one containing four and the other eight propositions, and their propositional analyses. Based on Kintsch and Keenan. \({ }^{[95]}\)

Figure 1707.3: Reading time (in seconds) and recall time for sentences containing different numbers of propositions (straight lines represent a least squares fit; for reading \(t=6.37+.94 P_{\text {pres }}\), and for recall \(t=5.53+1.48 P_{\text {rec }}\) ). Adapted from Kintsch and Keenan. \({ }^{[95]}\)

Figure 1707.4: Percentage of correct subject responses to the pronoun reference questions as a function of the number of sentences between the pronoun and the referent noun. Plotted lines are various subject reading spans. Adapted from Daneman and Carpenter. \({ }^{[49]}\)

Figure 1707.5: Percentage of correct answers as a function of subject's reading span and the presence or absence of a sentence boundary. Adapted from Daneman and Carpenter. \({ }^{[50]}\)

Figure 1707.6: Example of an object layout and the corresponding ordered tree for one of the subjects. Based on McNamara, Hardy, and Hirtle. \({ }^{[120]}\)

Figure 1707.7: Visible difference in offset of last non-space character on a line between successive lines, in the visible form of the .c files (horizontal tab characters were mapped to 8 space characters), for lines of various lengths, i.e., those whose previous line contained 60 or more characters, and those whose previous line contains less than 20 characters. There are ten times fewer lines sharing the same right offset as sharing the same left offset (see Figure 1707.8). Based on the visible form of the .c files.

Figure 1707.8: Visible difference in relative indentation of first non-space character on a line between successive lines in the visible form of the .c files (horizontal tab characters were mapped to 8 space characters). The smaller peaks around zero are indentation differences of two characters. The wider spaced peaks have a separation of eight characters. Individual files had more pronounced peaks. Based on the visible form of the .c files.

Figure 1707.9: Number of function definitions containing a given number of each kind of statement. Based on the translated form of this book's benchmark programs.

\section*{1740 A selection statement selects among a set of statements depending on the value of a controlling expression. \\ Usage}

In the translated form of this book's benchmark programs \(1.3 \%\) of selection-statements and \(4 \%\) of iteration-statements have a controlling expression that is a constant expression. Use of simple, noniterative, flow analysis enables a further \(0.6 \%\) of all controlling expressions to be evaluated to a constant
expression at translation time.

In the else form, the second substatement is executed if the expression compares equal to 0 .

\section*{Usage}

In the visible form of the .c files \(21.5 \%\) of if statements have an else form. (Counting all forms of if supported by the preprocessor, with \#elif counting as both an if and an else, there is an \#else form in \(25.0 \%\) of cases.)

The controlling expression of a switch statement shall have integer type.

Figure 1748.1: Density of case label values (calculated as (maximum case label value minus minimum case label value minus one) divided by the number of case labels associated with a switch statement) and span of case label values (calculated as (maximum case label value minus minimum case label value minus one)). Based on the translated form of this book's benchmark programs and embedded results from Engblom \({ }^{[60]}\) (which were scaled, i.e., multiplied by a constant, to allow comparison). The no default results were scaled so that the total count of switch statements matched those that included a default label.

Figure 1748.2: Number of case/default labels having s given number of statements following them (statements from any nested switch statements did not contribute towards the count of a label). Based on the visible form of the .c files.

Table 1748.1: Occurrence of switch statements having a controlling expression of the given type (as a percentage of all switch statements). Based on the translated form of this book's benchmark programs.
\begin{tabular}{lrlr}
\hline Type & \(\%\) & Type & \% \\

char & 5.1 & & \\
\hline
\end{tabular}

1751 There may be at most one default label in a switch statement.
default label at most one

\section*{Usage}

In the visible form of the .c files, \(72.8 \%\) of switch statements contain a default label.

1753 A switch statement causes control to jump to, into, or past the statement that is the switch body, depending on the value of a controlling expression, and on the presence of a default label and the values of any case labels on or in the switch body.

Table 1753.1: Performance comparison (in seconds) of some implementation techniques for a series of if statements (contained in a loop that iterated \(10,000,000\) times) using (1) linear search (LS), or (2) indirect jump (IJ), for a variety of processors in the SPARC family. \(b r\) is the average number of branches per loop iteration. Based on Uh and Whalley. \({ }^{[170]}\)

\section*{Usage}

Numbers such as those given in Table 1782.1 and Table 1782.2 depend on the optimizations performed by an implementation. For instance, unrolling a frequently executed loop will reduce the percentage of branch instructions.

Figure 1782.1: Number of function definitions containing a given number of jump-statements. Based on the translated form of this book's benchmark programs.

Figure 1782.2: Number of iteration-statement containing the given number of break and continue Based on the visible form of the .c files.

Table 1782.1: Dynamic occurrence of different kinds of instructions that can change the flow of control. \%Instructions Altering Control Flow is expressed as a percentage of all executed instructions. All but the last row are expressed as percentages of these, control flow altering, instructions only. The kinds of instructions that change control flow are: conditional branches \(C B\), unconditional branches \(U B\), indirect procedure calls \(I C\), procedure calls \(P C\), procedure returns Ret, and other breaks Oth (e.g., signals and switch statements). Instructions between branches is the mean number of instructions between conditional branches. Based on Calder, Grunwald, and Zorn. \({ }^{[27]}\)

1783 A jump statement causes an unconditional jump to another place.
jump statement causes jump to

\section*{Usage}

A study by on Gellerich, Kosiol, and Ploedereder \({ }^{[72]}\) analyzed goto usage in Ada and C. In the translated form of this book's benchmark programs \(20.6 \%\) of goto statements jumped to a label that occurred textually before them in the source code.

\section*{1800 A return statement without an expression shall only appear in a function whose return type is void. Usage}

The translated form of this book's benchmark programs contained 19 instances of a return statement without an expression appearing in a function whose return type was void.

Figure 1783.1: Number of goto statements having a given number of visible source lines between a goto statement and its destination label (negative values denote backward jumps). Based on the translated form of this book's benchmark programs.

Figure 1783.2: Number of goto statements and labels having a given scope nesting level (nesting level 1 is the outermost block of a function definition), and on the right the difference in scope levels between a goto statement and its corresponding labeled statement (negative values denote a jump to a less nested scope). Based on the translated form of this book's benchmark programs.
translation-unit:
external-declaration translation-unit external-declaration
external-declaration:
function-definition declaration

\section*{Usage}

On a large development project it is possible that more than one person will write some set of functions performing similar operations. This duplication of functionality occurs at a higher-level than copying and reusing sequences of statements (discussed elsewhere), it is a concept that is being duplicated. Marcus and Maletic \({ }^{[116]}\) used latent semantic analysis to identify related source files (what they called concept clones). Source code identifiers and words in comments were used as input to the indexing process. An analysis of the Mozilla source code highlighted two different implementations of linked list functions and four files that contained their own implementations.

Figure 1810.1: Number of translation units containing a given number of external-declarations and function-definitions declarations (rounded to the nearest fifty and excluding identifiers declared in any system headers that are \#included). Based on the translated form of this book's benchmark programs.

Figure 1810.2: Number of translation units containing a given number of function definitions and percentage of functions that are called within the translation unit that defines them. Based on the translated form of this book's benchmark programs.

\hline
\end{tabular}

1878 After all replacements due to macro expansion and the defined unary operator have been performed, all remaining identifiers (including those lexically identical to keywords) are replaced with the pp-number \(\mathbf{0}\), and then each preprocessing token is converted into a token.

\section*{Usage}

Approximately \(15 \%\) of all conditional inclusion directives, in the translated form of this book's benchmark programs, contained an identifier that was replaced by 0 (i.e., they contained an identifier that was neither the operand of defined or defined as macro names).

1889 If it evaluates to false (zero), the group that it controls is skipped: directives are processed only through the name that determines the directive in order to keep track of the level of nested conditionals;

1896 A \#include directive shall identify a header or source file that can be processed by the implementation.

Figure 1889.1: Number of top-level source files (i.e., the contents of any included files are not counted) and (right) complete translation units (including the contents of any files \#included more than once) having a given number of lines skipped during translation of this book's benchmark programs.

Figure 1896.1: Number of times the same header was \#included during the translation of a single translation unit. The crosses denote all headers (i.e., all systems headers are counted), triangles denote all headers delimited by quotes (i.e., likely to be user defined headers) and bullets denote all quote delimited headers \#include nested at least three levels deep. Based on the translated form of this book's benchmark programs.

Figure 1896.2: Number of preprocessing translation units (excluding system headers) containing a given number of \#includes whose contents are not referenced during translation (excludes the case where the same header is \#included more than once, see Figure 1896.1). Based on the translated form of this book's benchmark programs.

Figure 1896.3: Number of . c source files containing a given number of \#include directives (dashed lines represent number of unique headers). Based on the visible form of the .c files.

Figure 1896.4: header-name rank (based on character sequences appearing in \#include directives) plotted against the number of occurrences of each character sequence. Also see Figure 792.26. Based on the visible form of the .c files.

Table 1896.1: Occurrence of two forms of header-names (as a percentage of all \#include directives), the percentage of each kind that specifies a path to the header file, and number of absolute paths specified. Based on the visible form of the .c files.
\begin{tabular}{lrrc}
\hline Header Form & \% Occurrence & \% Uses Path & Number Absolute Paths \\
\hline <h-char-sequence> & 75.0 & 86.4 & 0 \\
"q-char-sequence" & 25.0 & 17.2 & 0 \\
\hline
\end{tabular}

1897 A preprocessing directive of the form
\# include <h-char-sequence> new-line
searches a sequence of implementation-defined places for a header identified uniquely by the specified sequence between the < and > delimiters, and causes the replacement of that directive by the entire contents of the header.

Table 1897.1: Number of various kinds of identifiers declared in the headers contained in the /usr/include directory of some translation environments. Information was automatically extracted and represents an approximate lower bound. Versions of the translation environments from approximately the same year (mid 1990s) were used. The counts for ISO C assumes that the minimum set of required identifiers are declared and excludes the type generic macros.
\begin{tabular}{lrrrrrr}
\hline Information & Linux 2.0 & AIX on RS/6000 & HP/UX 9 & SunOS 4 & Solaris 2 & ISO C \\
\hline Number of headers & 2,006 & 1,514 & 1,264 & 987 & 1,495 & 24 \\
macro definitions & 10,252 & 18,637 & 13,314 & 11,987 & 10,903 & 446 \\

\hline
\end{tabular}

1931 A preprocessing directive of the form
\# define identifier replacement-list new-line
defines an object-like macro that causes each subsequent instance of the macro name \({ }^{146)}\) to be replaced by the replacement list of preprocessing tokens that constitute the remainder of the directive.

Figure 1931.1: Number of translation units containing a given number of macro names which were macro expanded, excluding expansions that occurred while processing the contents of system headers. Based on the translated form of this book's benchmark programs.

\section*{Usage}

Table 1931.1: Detailed breakdown of the kinds of replacement lists occurring in macro definitions. Adapted from Ernst, Badros, and Notkin. \({ }^{[63]}\)
\begin{tabular}{lcl}
\hline Replacement List & \(\%\) & Example \\
\hline constant & 42 & \#define ARG_MAX 1000 \\
expression & 33 & \#define SHFT_UP(x) ( x\() \quad \ll 8)\) \\
empty & 6.9 & \#define DUMMY \\
unknown identifier & 6.9 & \#define INTERN_BUF buffer \\
statement & 5.1 & \#define TERMINATE goto func_end \\
type & 2.1 & \#define NODE_PTR void * \\
other & 1.9 & \#define OPTION -X=23 \\
symbol & 1.4 & \#define ALLOC_STORAGE malloc \\
syntactic & 0.5 & \#define begin \{ \\
\hline
\end{tabular}

Table 1931.2: Common macro definitions listed with an abstracted form of their replacement list (as a percentage of all macro definitions). Note that function-call may also be a macro invocation. Based on the visible form of the .c and .h files.
\begin{tabular}{lr}
\hline Kind of Macro Defined and Abstract Form of its Replacement List & \(\%\) \\
\hline object-like macro integer-constant & 50.7 \\
object-like macro identifier & 5.9 \\
object-like macro expression & 5.8 \\
function-like macro function-call & 4.7 \\
object-like macro function-call & 3.7 \\
object-like macro string-literal & 3.4 \\
function-like macro expression & 3.4 \\
object-like macro & 3.4 \\
object-like macro constant-expression & 2.0 \\
function-like macro & 1.7 \\
others & 15.4 \\
\hline
\end{tabular}

\section*{Usage}

Usage information on the number of parameters in function-like macro definitions is given elsewhere.

1950 Each \# preprocessing token in the replacement list for a function-like macro shall be followed by a parameter as the next preprocessing token in the replacement list.

\section*{Usage}

Based on the visible form of the .c files \(0.26 \%\) ( \(0.09 \%\).h files) of the replacement lists of macro definitions contained a \# operator. There were no obvious patterns to the usage.

1958 A \#\# preprocessing token shall not occur at the beginning or at the end of a replacement list for either form of macro definition.

Table 1958.1: Occurrence of the \#\# preprocessor operator (as a percentage of all occurrences of that operator). The form , \#\# identifier is a gcc extension (described in the Common implementations subclause). Based on the visible form of the .c and . h files.
\begin{tabular}{lr}
\hline Preprocessing Token Sequence & \(\%\) \\
\hline identifier \#\# identifier & 70.2 \\
, \#\# identifier & 24.2 \\
identifier \#\# identifier \#\# identifier & 15.7 \\
others & 4.8 \\
integer-constant \#\# identifier & 1.8 \\
integer-constant \#\# identifier \#\# integer-constant & 1.0 \\
identifier \#\# integer-constant & 1.0 \\
\hline
\end{tabular}

1961 For both object-like and function-like macro invocations, before the replacement list is reexamined for more macro names to replace, each instance of a \#\# preprocessing token in the replacement list (not from an argument) is deleted and the preceding preprocessing token is concatenated with the following preprocessing token.

Table 1961.1: Possible results of concatenating, using the \#\# operator, pairs of preprocessing tokens (the one appearing in the left column followed by the one appearing in the top row) where the result might be defined (undefined denotes undefined behavior).
\begin{tabular}{|c|c|c|c|c|c|}
\hline & identifier & pp-number & punctuator & string-literal & character-constant \\
\hline identifier & identifier & identifier or undefined & undefined & string-literal or undefined & character-constant or undefined \\
\hline pp-number & pp-number & pp-number & pp-number or undefined & undefined & undefined \\
\hline punctuator & pp-number or undefined & pp-number or undefined & punctuator or undefined & undefined & undefined \\
\hline everything else & undefined & undefined & undefined & undefined & undefined \\
\hline
\end{tabular}

1976 A preprocessing directive of the form
\# undef identifier new-line
causes the specified identifier no longer to be defined as a macro name.

\section*{Usage}

Approximate 5\% of all \#undef directives occur before a \#include directive (based on the visible form of the .c files).
macro name predefined

Table 1976.1: Occurrence of various sequences of preprocessing directives (as a percentage of all such sequences) that follow a \#undef and reference the same identifier (e.g., \(2.7 \%\) of the first occurrence of \#undef are followed by one or more \#defines followed by one or more \#undefs). \#define represents one or more \#define preprocessing directives. \#undef represents one or more \#undef preprocessing directives. \#if[n]def represents two or more \#ifs and \#ifndefs, in any order. \#und-def represents one or more pairs of \#undef \#define preprocessing directives. Based on the visible form of the .c files.
\begin{tabular}{lr}
\hline Following Directive Sequences & \(\%\) \\
\hline & 53.0 \\
\#ifdef & 20.4 \\
\#define & 16.2 \\
others & 4.8 \\
\#define \#undef & 2.7 \\
\#if(n)def & 1.5 \\
\#define \#undef-\#define \#undef & 1.4 \\
\hline
\end{tabular}

The following macro names \({ }^{151)}\) shall be defined by the implementation:
Table 2004.1: Occurrence of predefined macro names (as a percentage of all predefined macro names; a total of 1,826 ). Based on the visible form of the .c and .h files.

\hline
\end{tabular}

2175 The header <ctype.h>declares several functions useful for classifying and mapping characters.166) In all cases the argument is an int, the value of which shall be representable as an unsigned char or shall equal the value of the macro EOF. If the argument has any other value, the behavior is undefined.

Figure 2175.1: Interrelationships between the character handling functions.

Additional macro definitions, beginning with \(E\) and a digit or \(E\) and an uppercase letter,171) may also be specified by the implementation.

\section*{Usage}

See Future Library Directions for reserved identifier usage information.

\section*{Each of the macros}

FE_DOWNWARD FE_TONEAREST FE_TOWARDZERO FE_UPWARD
is defined if and only if the implementation supports getting and setting the represented rounding direction by means of the fegetround and fesetround functions. Additional implementation-defined rounding directions, with macro definitions beginning with FE_ and an uppercase letter, may also be specified by the implementation. The defined macros expand to integer constant expressions whose values are distinct nonnegative values.174)

\section*{Usage}

Usage information on reserved identifier spellings is given elsewhere (see Table 98.1).
Additional implementation-defined environments, with macro definitions beginning with \(F E_{-}\)and an uppercase letter, and having type "pointer to const-qualified fenv_t", may also be specified by the implementation.

\section*{Usage}

Usage information on reserved identifier spellings is given elsewhere (see Table 98.1).

The header <math. \(\mathrm{h}>\) declares two types and many mathematical functions and defines several macros. Most synopses specify a family of functions consisting of a principal function with one or more double parameters, a double return value, or both; and other functions with the same name but with \(f\) and \(I\) suffixes, which are corresponding functions with float and long double parameters, return values, or both.189) Integer arithmetic functions and conversion functions are discussed later.

\section*{Usage}

A study by Citron and Feitelson \({ }^{[40]}\) (based on the SPEC CFP95, Khoros, and MediaBench suites) found that on average \(82 \%\) of calls to functions in the maths library, by a program, had the same argument values as previous calls to those function, by the same program.

An implementation need not generate any of these signals, except as a result of explicit calls to the raise
specified by the implementation. The complete set of signals, their semantics, and their default handling is implementation-defined; all signal numbers shall be positive.

\section*{Usage}

See Future Library Directions for reserved identifier usage information.
2590 The header <stdio.h>declares three types, several macros, and many functions for performing input and output.

\section*{Usage}

A study Pasquale and Polyzos \({ }^{[134]}\) looked at the I/O characteristics of scientific applications, a study by Hsu, Smith, and Young \({ }^{[86]}\) measured I/O behavior for production database workloads, while Ruemmler and Wilkes \({ }^{[146]}\) looked at disk access patterns.

2839 The order and contiguity of storage allocated by successive calls to the calloc, malloc, and realloc functions is unspecified. The pointer returned if the allocation succeeds is suitably aligned so that it may be assigned to a pointer to any type of object and then used to access such an object or an array of such objects in the space allocated (until the space is explicitly deallocated). The lifetime of an allocated object extends from the allocation until the deallocation. Each such allocation shall yield a pointer to an object disjoint from any other object. The pointer returned points to the start (lowest byte address) of the allocated space. If the space cannot be allocated, a null pointer is returned. If the size of the space requested is zero, the behavior is implementation-defined: either a null pointer is returned, or the behavior is as if the size were some nonzero value, except that the returned pointer shall not be used to access an object.

Table 2839.1: Memory management function usage. mallocs is the number of calls to the malloc library function, frees the number of calls to the free library function, and size the mean number of bytes of the objects allocated. Based on Calder, Grunwald, and Zorn. \({ }^{[27]}\)

    ## Commentary

    The phrase at the time of writing is sometimes used. For this version of the material this time should be taken to mean no later than December 2008.
    

    With the introduction of new devices and extended character sets, new features may be added to this International Standard. Subclauses in the language and library clauses warn implementors and programmers of usages which, though valid in themselves, may conflict with future additions.

    Certain features are obsolescent, which means that they may be considered for withdrawal in future revisions of this International Standard. They are retained because of their widespread use, but their use in new implementations (for implementation features) or new programs (for language [6.11] or library features [7.26]) is discouraged.

    This International Standard is divided into four major subdivisions:

    - preliminary elements (clauses 1-4);
    - the characteristics of environments that translate and execute C programs (clause 5);
    - the language syntax, constraints, and semantics (clause 6);
    — the library facilities (clause 7).
    Examples are provided to illustrate possible forms of the constructions described. Footnotes are provided to emphasize consequences of the rules described in that subclause or elsewhere in this International Standard. References are used to refer to other related subclauses. Recommendations are provided to give advice or guidance to implementors. Annexes provide additional information and summarize the information contained in this International Standard. A bibliography lists documents that were referred to during the preparation of the standard.

    The language clause (clause 6) is derived from "The C Reference Manual".
    The library clause (clause 7) is based on the 1984 /usr/group Standard.

    1. Introduction ..... 20
    1.1. Characteristics of the source code ..... 23
    1.2. What source code to measure? ..... 24

    ## Usage

    ## 1 Introduction

    This subsection provides some background on the information appearing in the Usage subsections of this book. The purpose of this usage information is two-fold:

    1. To give readers a feel for the common developer usage of C language constructs. Part of the process of becoming an experienced developers involves learning about what is common and what is uncommon. However, individual experiences can be specific to one application domain, or company cultures.

    2. To provide frequency-of-occurrence information that could be used as one of the inputs to cost/benefit decisions (i.e., should a guideline recommendation be made rather than what recommendation might be made). This is something of a chicken-and-egg situation in that knowing what measurements to make requires having potential guideline recommendations in mind, and the results of measurements may suggest guideline recommendations (i.e., some construct occurs frequently).

    Almost all published measurements on C usage are an adjunct to a discussion of some translator optimization technique. They are intended to show that the optimization, which is the subject of the paper, is worthwhile because some constructs occurs sufficiently often for an optimization to make worthwhile savings, or that some special cases can be ignored because they rarely occur. These kinds of measurements are usually discussed in the Common implementation subsections. One common difference between the measurements in Common Implementation subsections and those in Usage subsections is that the former are often dynamic (instruction counts from executing programs), while the latter are often static (counts based on some representation of the source code).
    There have been a few studies whose aim has been to provide a picture of the kinds of C constructs that commonly occur (e.g., preprocessor usage, ${ }^{[63]}$ embedded systems ${ }^{[61]}$ ). These studies are quoted in the relevant C sentences. There have also been a number of studies of source code usage for other algorithmic languages, Assembler, ${ }^{[48]}$ Fortran, ${ }^{[99]} \mathrm{PL} / 1,{ }^{[59]}$ Cobol ${ }^{[4,38,88]}$ (measurements involving nonalgorithmic languages have very different interests ${ }^{[32,41]}$ ). These are of interest in studying cross-language usage, but they are not discussed in this book. In some cases a small number of machine code instruction sequences (which might be called idioms) have been found to account for a significant percentage of the instructions executed during program execution. ${ }^{[153]}$
    The intent here is to provide a broad brush picture. On the whole, single numbers are given for the number of occurrences of a construct. In most cases there is no break down by percentage of functions, source files, programs, application domain, or developer. There is variation across all of these (e.g., application domain and individual developer). Whenever this variation might be significant, additional information is given. Those interested in more detailed information might like to make their own measurements.
    Many of the coding guideline recommendations made in this book apply to the visible source code as seen by the developer. For these cases any usage measurements also apply to the visible source code. The effects of any macro replacement, conditional inclusion, or \#included header are ignored. Each usage subsection specifies what the quoted numbers apply to (usually either visible source, or the tokens processed during translation phase 7).
    In practice many applications do not execute in isolation; there is usually some form of operating system that is running concurrently with it. The design of processor instruction sets often takes task-switching and other program execution management tasks into account. In practice the dynamic profile of instructions executed by a processor reflects this mix of usage, ${ }^{[17]}$ as does the contents of its cache. ${ }^{[117]}$

    ### 1.1 Characteristics of the source code

    All source code may appear to look the same to the casual observer. An experienced developer will be aware of recurring patterns; source can be said to have a style. Several influences can affect the characteristics of source code, including the following:

    - Use of extensions to the C language and differences, for prestandard C, from the standard (often known as $K \& R C$ ). Some extensions eventually may be incorporated into a revised version of the standard; for instance, long long was added in C99. Some extensions are specific to the processor on which the translated program is to execute.
    coding guidelines applications
    coding guidelines coding style
    - The application domain. For instance, scientific and engineering applications tend to make extensive use of arrays and spend a large amount of their time in loops processing information held in these arrays; screen based interactive applications often contain many calls to GUI library functions and can spend more time in these functions than the developer's code; data-mining applications can spend a significant amount of time searching large data structures.
    - How the application is structured. Some applications consist of a single, monolithic, program, while others are built from a collection of smaller programs sharing data with one another. These kinds of organization affect how types and objects are defined and used.
    - The extent to which the source has evolved over time. Developers often adopt the low-risk strategy of making the minimal number of changes to a program when modifying it. Often this means that functions and sequences of related statements tend to grow much larger than would be the case if they had been written from scratch, because no restructuring is performed.
    - Individual or development group stylistic usage. These differences can include the use of large or small functions, the use of enumeration constants or object-like macros, the use of the smallest integer type required rather than always using int, and so forth.

    ### 1.2 What source code to measure?

    This book is aimed at a particular audience and the source code they are likely to be actively working on. This audience will be working on C source that has been written by more than one developer, has existed for a year or more, and is expected to continue to be worked on over the coming years.
    benchmarks The benchmarks used in various application areas were written with design aims that differ from those of this book. For instance, the design aim behind the choice of programs in the SPEC CPU benchmark suite was to measure processor, memory hierarchy, and translator performance. Many of these programs were written by individuals, are relatively short, and have not changed much over time.
    Although there is a plentiful supply of C source code publicly available (an estimated 20.3 million C source files on the Web ${ }^{[18]}$ ), this source is nonrepresentative in a number of ways, including:

    - The source has had many of the original defects removed from it. The ideal time to make these measurements is while the source is being actively developed.
    - Software for embedded systems is often so specialized (in the sense of being tied to custom hardware), or commercially valuable, that significant amounts of it are not usually made publicly available.

    Nevertheless, a collection of programs was selected for measurement, and the results are included in this book (see Table 0.23). The programs used for this set of measurements have reached the stage that somebody has decided that they are worth releasing. This means that some defects in the source, prior to the release, will not be available to be included in these usage figures.

    Table 0.23: Programs whose source code (i.e., the .c and .h files) was used as the input to measurement tools (operating on either the visible or translated forms), whose output was used to generate this book's usage figures and tables.

    | Name | Application Domain | Version |
    | :--- | :--- | :--- |
    | gcc | C compiler | 2.95 |
    | idsoftware | Games programs, e.g., Doom |  |
    | linux | Operating system | 2.4 .20 |
    | mozilla | Web browser | 1.0 |
    | openafs | File system | 1.2 .2 a |
    | openMotif | Window manager | 2.2 .2 |
    | postgresql | Database system | 6.5 .3 |

    Table 0.24: Source files excluded from the Usage measurements.

    | Files | Reason for Exclusion |
    | :--- | :--- |
    | gcc-2.95/libio/tests/tfformat.c | a list of approximately 4,000 floating constants |
    | gcc-2.95/libio/tests/tiformat.c | a list of approximately 5,000 hexadecimal constants |

    

    Figure 64.1: Some exactly representable values and three values $(a, b$, and $c)$ that are not exactly representable.

    Table 0.25: Character sequences used to denote those operators and punctuators that perform more than one role in the syntax.

    | Symbol | Meaning | Symbol | Meaning |
    | :--- | :--- | :--- | :--- |
    | $\mathbf{+ + \mathbf { v }}$ | prefix ++ | $\mathbf{- - v}$ | prefix -- |
    | $\mathbf{v + +}$ | postfix ++ | $\mathbf{v - -}$ | postfix -- |
    | $\mathbf{- v}$ | unary minus | $\mathbf{+ v}$ | unary plus |
    | "v | indirection operator | *p | star in pointer declaration |
    | $\& \mathbf{v}$ | address-of |  |  |
    | $\mathbf{: \mathbf { b }}$ | colon in bitfield declaration | $\mathbf{? :}$ | colon in ternary operator |

    ## 42 implementation-defined behavior

    unspecified behavior where each implementation documents how the choice is made

    ## Usage

    Annex J. 3 lists 97 implementation-defined behaviors.

    ## 46 undefined behavior

    behavior, upon use of a nonportable or erroneous program construct or of erroneous data, for which this International Standard imposes no requirements

    ## Usage

    Annex J. 2 lists 190 undefined behaviors.

    49 unspecified behavior
    use of an unspecified value, or other behavior where this International Standard provides two or more possibilities and imposes no further requirements on which is chosen in any instance

    ## Usage

    Annex J. 1 lists 50 unspecified behaviors.

    ## 63 constraint

    restriction, either syntactic or semantic, by which the exposition of language elements is to be interpreted

    ## Usage

    There are 134 instances of the word shall in a Constraints clause (out of 588 in the complete standard). This places a lower bound on the number of constraints that can be violated (some uses of shall describe more than one kind of construct).

    ## 64 correctly rounded result

    representation in the result format that is nearest in value, subject to the effectivecurrent rounding mode, to what the result would be given unlimited range and precision

    82 In this International Standard, "shall" is to be interpreted as a requirement on an implementation or on a program;

    ## Usage

    The word shall occurs 537 times (excluding occurrences of shall not) in the C Standard.
    conversely, "shall not" is to be interpreted as a prohibition.

    ## Usage

    The phrase shall not occurs 51 times (this includes two occurrences in footnotes) in the C Standard.

    The word shall appears 454 times outside of a Constraint clause; however, annex J. 2 only lists 190 undefined behaviors. The other uses of the word shall apply to requirements on implementations, not programs.
    3) This implies that a conforming implementation reserves no identifiers other than those explicitly reserved in this International Standard.
    

    Figure 92.1: A conforming implementation (gray area) correctly handles all strictly conforming programs, may successfully translate and execute some of the possible conforming programs, and may include some of the possible extensions.

    Table 98.1: Number of developer declared identifiers (the contents of any header was only counted once) whose spelling (the notation $[a-z]$ denotes a regular expression, i.e., a character between $a$ and $z$ ) is reserved for use by the implementation or future revisions of the C Standard. Based on the translated form of this book's benchmark programs.

    | Reserved spelling | Occurrences |
    | :--- | ---: |
    | Identifier, starting with __, declared to have any form | 3,071 |
    | Identifier, starting with _[A-Z], declared to have any form | 10,255 |
    | Identifier, starting with wcs[a-z], declared to have any form | 1 |
    | Identifier, with external linkage, defined in C99 | 12 |
    | File scope identifier or tag | 6,832 |
    | File scope identifier | 2 |
    | Macro name reserved when appropriate header is \#included | 6 |
    | Possible macro covered identifier | 144 |
    | Macro name starting with E[A-Z] | 339 |
    | Macro name starting with SIG[A-Z] | 2 |
    | Identifier, starting with is[a-Z], with external linkage (possibly macro covered) | 47 |
    | Identifier, starting with mem[a-Z], with external linkage (possibly macro covered) | 108 |
    | Identifier, starting with str[a-z], with external linkage (possibly macro covered) | 904 |
    | Identifier, starting with to[a-z], with external linkage (possibly macro covered) | 338 |
    | Identifier, starting with is[a-Z], with external linkage | 33 |
    | Identifier, starting with mem[a-z], with external linkage | 7 |
    | Identifier, starting with str[a-z], with external linkage | 28 |
    | Identifier, starting with to[a-z], with external linkage | 62 |

    107 A C program need not all be translated at the same time.
    program not translated at same time

    ## Usage

    A study by Linton and Quong ${ }^{[113]}$ used an instrumented make program to investigate the characteristics of programs (written in a variety of languages, including C) built over a six-month period at Stanford University. The results (see Figure 107.1) showed that approximately $40 \%$ of programs consisted of three or fewer translation units.

    116 1. Physical source file multibyte characters are mapped, in an implementation-defined manner, to the source translation phase character set (introducing new-line characters for end-of-line indicators) if necessary.
    

    Figure 107.1: Number of programs built from a given number of translation units. Adapted from Linton. ${ }^{[113]}$

    Table 116.1: Total number of characters and new-lines in the visible form of the .c and .h files.

    |  | .c files | .h files |
    | :--- | ---: | ---: |
    | total characters | $192,165,594$ | $64,429,463$ |
    | total new-lines | $6,976,266$ | $1,811,790$ |
    | non-comment characters | $144,568,262$ | $43,485,916$ |
    | non-comment new-lines | $6,113,075$ | $1,491,192$ |

    ## trigraph sequences

    phase 1Trigraph sequences are replaced by corresponding single-character internal representations.
    Usage
    The visible form of the .c files contain 8 trigraphs (.h 0 ).
    translation phase physical source ine logical source line
    2. Each instance of a backslash character ( $\backslash$ ) immediately followed by a new-line character is deleted, splicing physical source lines to form logical source lines.

    ## Usage

    In the visible form of the .c files $0.21 \%$ (.h $4.7 \%$ ) of all physical lines are spliced. Of these line splices $33 \%$ (.h $7.8 \%$ ) did not occur within preprocessing directives (mostly in string literals).

    ## translation phase 3 <br> 3. The source file is decomposed into preprocessing tokens ${ }^{6)}$ and sequences of white-space characters (including comments). <br> Usage <br> The visible form of the .c files contain 30,901,028 (.h 8,338,968) preprocessing tokens (new-line not <br> preprocess-777 <br> ing tokens white space separation included); 531,677 (.h 248,877) /* */ comments, and 52,531 (.h 27,393) // comments. <br> Usage information on white space is given elsewhere. <br> translation phase <br> 6. Adjacent string literal tokens are concatenated. <br> Usage

    In the visible form of the .c files $4.9 \%$ (.h $15.6 \%$ ) of string literals are concatenated.
    All such translator output is collected into a program image which contains information needed for execution in its execution environment.
    
    

    Figure 118.1: Number of physical lines spliced together to form one logical line and the number of logical lines, of a given length, after splicing. Based on the visible form of the .c and .h files.

    Table 141.1: Total is the number of code pages in the application; Touched the number of code pages touched during startup; Utilization the average fraction of functions used during startup in each code page. Adapted from Lee. ${ }^{\text {[106] }}$

    | Application | Total | Touched (\%) | \% Utilization |
    | :--- | :--- | :--- | :--- |
    | acrobat | 404 | $246(60)$ | 28 |
    | netscape | 388 | $388(100)$ | 26 |
    | photoshop | 594 | $479(80)$ | 28 |
    | powerpoint | 766 | $164(21)$ | 32 |
    | word | 743 | $300(40)$ | 47 |

    164 It shall be defined with a return type of int and with no parameters:

    ```
    int main(void) { /* ... */ }
    ```

    ## Usage

    There was not a sufficiently large number of instances of main in the .c files to provide a reliable measure of the different ways this function is declared.

    190 An actual implementation need not evaluate part of an expression if it can deduce that its value is not used and that no needed side effects are produced (including any caused by calling a function or accessing a volatile object).

    221 Both the basic source and basic execution character sets shall have the following members: the 26 uppercase letters of the Latin alphabet

    | A | $\mathbf{B}$ | $\mathbf{C}$ | $\mathbf{D}$ | $\mathbf{E}$ | $\mathbf{F}$ | $\mathbf{G}$ | $\mathbf{H}$ | $\mathbf{I}$ | $\mathbf{J}$ | $\mathbf{K}$ | $\mathbf{L}$ | $\mathbf{M}$ |
    | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
    | $\mathbf{N}$ | $\mathbf{O}$ | $\mathbf{P}$ | $\mathbf{Q}$ | $\mathbf{R}$ | $\mathbf{S}$ | $\mathbf{T}$ | $\mathbf{U}$ | $\mathbf{V}$ | W | $\mathbf{X}$ | $\mathbf{Y}$ | $\mathbf{Z}$ |

    the 26 lowercase letters of the Latin alphabet

    | $\mathbf{a}$ | $\mathbf{b}$ | $\mathbf{c}$ | $\mathbf{d}$ | $\mathbf{e}$ | $\mathbf{f}$ | $\mathbf{g}$ | $\mathbf{h}$ | $\mathbf{i}$ | $\mathbf{j}$ | $\mathbf{k}$ | $\mathbf{l}$ | m |
    | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
    | $\mathbf{n}$ | $\mathbf{o}$ | $\mathbf{p}$ | $\mathbf{q}$ | $\mathbf{r}$ | $\mathbf{s}$ | $\mathbf{t}$ | $\mathbf{u}$ | $\mathbf{v}$ | $\mathbf{w}$ | $\mathbf{x}$ | $\mathbf{y}$ | $\mathbf{z}$ |

    the 10 decimal digits
    

    Figure 190.1: Number of parameters or locally defined objects that are not referenced within a function definition (left graph); number of objects declared in a scope that is wider than that needed for any of the references to them within a function definition (right graph). Based on the translated form of this book's benchmark programs.
    the following 29 graphic characters

    ```
    ! " # % & , ( ) * + , - . / :
    ; < = > [ \ ] ^ _ { | } ~
    ```

    the space character, and control characters representing horizontal tab, vertical tab, and form feed.

    Table 221.1: Occurrence of characters as a percentage of all characters and as a percentage of all noncomment characters (i.e., outside of comments). Based on the visible form of the .c files. For a comparison of letter usage in English language and identifiers see Figure 792.16.

    | Letter or ASCII Value | All | Noncomment | Letter or ASCII Value | All | Noncomment | Letter or ASCII Value | All | Noncomment | Letter or ASCII Value | All | Noncomment |

    233
    ??= \# ??) ] ??! |
    ??( [ ??' ^ ?? $<$ \}
    ??/ \ ?? $<$ ? ? - ~

    ## Usage

    There are insufficient trigraphs in the visible form of the .c files to enable any meaningful analysis of the usage of different trigraphs to be made.

    ## 234 No other trigraph sequences exist.

    ## Usage

    The visible form of the .c files contained 593 (.h 10) instances of two question marks (i.e., ??) in string literals that were not followed by a character that would have created a trigraph sequence.

    243- A multibyte character set may have a state-dependent encoding, wherein each sequence of multibyte characters begins in an initial shift state and enters other locale-specific shift states when specific multibyte characters are encountered in the sequence.
    multibyte character state-dependent encoding shift state

    Table 243.1: Commonly seen ISO 2022 Control Characters. The alternative values for SS2 and SS3 are only available for 8-bit codes.

    | Name | Acronym | Code Value | Meaning |
    | :--- | :--- | :--- | :--- |
    | Escape | ESC | $0 \times 1 \mathrm{~b}$ | Escape |
    | Shift-In | SI | $0 \times 0 f$ | Shift to the G0 set |
    | Shift-Out | SO | $0 \times 0 \mathrm{e}$ | Shift to the G1 set |
    | Locking-Shift 2 | LS2 | ESC 0x6e | Shift to the G2 set |
    | Locking-Shift 3 | LS3 | ESC 0x6f | Shift to the G3 set |
    | Single-Shift 2 | SS2 | ESC 0x4e, or 0x8e | Next character only is in G2 |
    | Single-Shift 3 | SS3 | ESC 0x4f, or 0x8f | Next character only is in G3 |

    Figure 293.1: Number of character string literals containing a given number of characters (i.e., their length). Based on the visible form of the .c files.
    

    Figure 294.1: Number of objects requiring the specified amount of storage. Based on the translated form of this book's benchmark programs, using integer types whose sizes were: sizeof(short) $==2$, sizeof(int) $==4$, and sizeof(long) $==4$; and alignment requirements that were a multiple of a types size.
    

    Nesting depth
    Figure 295.1: Number of \#include preprocessor directives, that contain the quote-delimited form of header name (occurrences of the <> delimited form were not counted), having a given nesting depth. Based on the translated form of this book's benchmark programs.
    

    Figure 296.1: Number of switch statements containing the given number of case labels (left) and number of individual statements labeled by a given number of case labels (right). Based on the visible form of the .c files. Note that counts do not include occurrences of the default label.

    ## Usage

    Measurements of classes, ${ }^{[173]}$ in large Java programs, have found that the number of members follows the same pattern as that in C (see Figure 297.1).

    - 1023 enumeration constants in a single enumeration

    299

    - 63 levels of nested structure or union definitions in a single struct-declaration-list

    303 The values given below shall be replaced by constant expressions suitable for use in \#if preprocessing directives.
    

    Figure 297.1: Number of structure and union type definitions containing the given number of members (members in any nested definitions are not included in the count of members of the outer definition). Based on the visible form of the .c and .h files.
    

    Figure 298.1: Number of enumeration types containing a given number of enumeration constants. Based on the visible form of the .c and .h files (also see Figure 1439.1).
    

    Figure 299.1: Number of structure and union type definitions containing the given number nested members that are textually structure and union type definitions (i.e., definitions using \{ \} not typedef names). Based on the visible form of the .c and .h files.

    Table 303.1: Number of identifiers defined as macros in <limits. $\mathrm{h}>$ (see Table 770.3 for information on the number of identifiers appearing in the source) appearing in the visible form of the .c and .h files.

    | Name | .c file | .h file | Name | .c file | .h file | Name | .c file | .h file |

    $334 e$ exponent (an integer between a minimum $e_{\min }$ and a maximum $e_{\max }$ )

    ## Usage

    The range of exponent values that can occur within programs may depend on the application domain. For instance, astronomy programs may contain ranges of very large values and subatomic particle programs contain ranges of very small values. A study of software for automotive control systems ${ }^{[45]}$ showed (see Table 334.1) a relatively small range of exponents, close to zero.

    Table 334.1: Dynamic distribution of decimal exponents, as a percentage, for operands of various floating point operations. Adapted from Connors, Yamada, and $\mathrm{Hwu}^{[45]}$ (thanks to Connors for supplying the raw data).

    | Exponent | Compare | Add | Multiply | Divide | Exponent | Compare | Add | Multiply | Divide |
    | :---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
    | 0 | 15.60 | 11.4 | 6.7 | 3.0 |  |  |  |  |  |
    | -1 | 2.5 | 2.5 | 1.9 | 0.0 | 1 | 10.80 | 9.3 | 1.6 | 1.0 |

    | $\mathrm{A} 23=\mathrm{A} 22 / 2$ | $0.00000000000000000000011 \times 2^{-126}$ | 0 | Exact result |
    | A24 $=$ A23 / 2 | $0.00000000000000000000010 \times 2^{-126}$ | 0 | Inexact* |
    | A25 = A24 / 2 | $0.00000000000000000000001 \times 2^{-126}$ | 0 | Exact result |
    | A26 = A25 / 2 | 0.0 | 0 | Inexact* | operations accuracy

    The accuracy of the floating-point operations (+, -, *, /) and of the library functions in <math.h> and <complex.h> that return floating-point results is implementation-defined, as is the accuracy of the conversion between floating-point internal representations and string representations performed by the library routine in <stdio.h>, <stdlib.h> and <wchar.h>.

    ## Usage

    In theory it is possible to measure the accuracy required/expected by an application. However, it is not possible to do this automatically - it requires detailed manual analysis. Consequently, there are no usage figures for this sentence (because no such analyses have been carried out by your author for any of the programs in the measurement set).

    Table 352.1: Effect of rounding mode (FLT_ROUNDS taking on values $0,1,2$, or 3 ) on the result of a single precision value (given in the left column).

    |  | 0 | 1 | 2 | 3 |
    | ---: | ---: | :--- | :--- | :--- |
    | 1.00000007 | 1.0 | 1.00000012 | 1.00000012 | 1.0 |
    | 1.00000003 | 1.0 | 1.0 | 1.00000012 | 1.0 |
    | -1.00000003 | -1.0 | -1.0 | -1.0 | -1.00000012 |
    | -1.00000007 | -1.0 | -1.00000012 | -1.0 | -1.00000012 |

    368 - number of decimal digits, $n$, such that any floating-point number in the widest supported floating type with $p_{\text {max }}$ radix $b$ digits can be rounded to a floating-point number with $n$ decimal digits and back again without change to the value,

    $$
    \begin{cases}p_{\max } \log _{10} b & \text { if } b \text { is a power of } 10 \\ \left\lceil 1+p_{\max } \log _{10} b\right\rceil & \text { otherwise }\end{cases}
    $$

    DECIMAL_DIG 10

    389 A summary of the language syntax is given in annex A.

    397 The same identifier can denote different entities at different points in the program.

    407 If the declarator or type specifier that declares the identifier appears outside of any block or list of parameters, the identifier has file scope, which terminates at the end of the translation unit.

    408 If the declarator or type specifier that declares the identifier appears inside a block or within the list of parameter declarations in a function definition, the identifier has block scope, which terminates at the end of the associated block.

    413 the entity declared in the outer scope is hidden (and not visible) within the inner scope.

    ## Usage

    In the translated form of this book's benchmark programs there were 1,945 identifier definitions (out of 270,394 identifiers defined in block scope) where an identifier declared in an inner scope hid an identifier declared in an outer block scope.

    420 An identifier declared in different scopes or in the same scope more than once can be made to refer to the same object or function by a process called linkage. ${ }^{21)}$
    

    Figure 368.1: Representable powers of 10 and powers of 2 on the real line.
    

    Figure 389.1: Attributes a C language identifier can have.
    

    Figure 397.1: All combinations of linkage, scope, and name space that all possible kinds of identifiers, supported by C, can have. $\mathbf{M}$ refers to the members of a structure or union type. There is a separate name space for macro names and they have no linkage, but their scope has no formally specified name.
    

    Figure 397.2: Number of declarations of an identifier with the same spelling in the same translation unit. Based on the translated form of this book's benchmark programs. Note that members of the same type are likely to be counted more than once (i.e., they are counted in every translation unit that declares them), while parameters and objects declared within function definitions are likely to be only counted once.
    _

    #### Abstract

     

    

    路 $\square$

    Table 420.1: Comparison of identifier linkage models

    | Model | File 1 | File 2 |
    | :---: | :---: | :---: |
    | common | extern int I ; int main() \{ $\mathrm{I}=1$; second() ; \} | extern int I; void second() \{ third( I ) ; \} |
    | Relaxed Ref/Def | int I; int main() \{ $\mathrm{I}=1$; second() ; \} | int I; void second() \{ third( I ); \} |
    | Strict Ref/Def | int I; int main() \{ I = 1; second(); \} | extern int I; void second() \{ third( I ) ; \} |
    | Initializer | int $\mathrm{I}=0$; int main() \{ $\mathrm{I}=1$; second(); \} | int I; void second() \{ third( I ); \} |

    421 There are three kinds of linkage: external, internal, and none.

    422 In the set of translation units and libraries that constitutes an entire program, each declaration of a particular identifier with external linkage denotes the same object or function.

    ## Usage

    A study of 29 Open Source programs by Srivastava, Hicks, Foster and Jenkins ${ }^{[154]}$ found 1,161 identifiers with external linkage, referenced in more than one translation unit, that were not declared in a header, and 809 instances where a header containing the declaration of a referenced identifier was not \#included (i.e., the source file contained a textual external declaration of the identifier).

    436 If, within a translation unit, the same identifier appears with both internal and external linkage, the behavior is undefined.

    ## Usage

    The translated form of this book's benchmark programs contained 27 instances of identifiers declared, within the same translation unit, with both internal and external linkage.

    438 If more than one declaration of a particular identifier is visible at any point in a translation unit, the syntactic context disambiguates uses that refer to different entities.
    

    Figure 421.1: Number of translation units containing a given number of objects and functions declared with internal and external linkage (excluding declarations in system headers). Based on the translated form of this book's benchmark programs.

    Table 438.1: Identifiers appearing immediately to the right of the given token as a percentage of all instances of the given token. An identifier appearing to the left of a : could be a label or a case label. However, C syntax is designed to be parsed from left to right and the presence, or absence, of a case keyword indicates the entity denoted by an identifier. Based on the visible form of the .c files.

    | Token | .c file | .h file | Token | .c file | .h file |
    | :--- | ---: | ---: | :--- | ---: | ---: |
    | goto identifier | 99.9 | 100.0 | struct identifier | 99.0 | 88.4 |
    | \#define identifier | 99.9 | 100.0 | union identifier | 65.5 | 75.8 |
    | . identifier | 100.0 | 99.8 | enum identifier | 86.6 | 53.6 |
    | -> identifier | 100.0 | 95.5 | case identifier | 71.3 | 47.2 |

    Thus, there are separate name spaces for various categories of identifiers, as follows:

    Table 439.1: Occurrence of various kinds of declarations of identifiers as a percentage of all identifiers declared in all the given contexts. Based on the translated form of this book's benchmark programs.

    | Declaration Context | \% | Declaration Context | \% |
    | :--- | ---: | :--- | ---: |
    | block scope objects | 23.7 | file scope objects | 4.4 |
    | macro definitions | 19.3 | macro parameters | 4.3 |
    | function parameters | 16.8 | enumeration constants | 2.1 |
    | struct/union members | 9.6 | typedef names | 1.2 |
    | function declarations | 8.6 | tag names | 1.0 |
    | function definitions | 8.1 | label names | 0.9 |

    # each structure or union has a separate name space for its members (disambiguated by the type of the expression used to access the member via the . or $->$ operator); 

    Table 443.1: Number of matches found when comparing between pairs of members contained in different Pascal records that were defined with the same type name. Adapted from Anquetil and Lethbridge. ${ }^{[7]}$

    |  | Member Types the Same | Member Types Different | Total |
    | :--- | ---: | ---: | ---: |
    | Member names the same | $73(94.8 \%)$ | $4(5.2 \%)$ | 77 |
    | Member names different | $52(11 \%)$ | $421(89 \%)$ | 473 |

    Table 443.2: Number of matches found when comparing between pairs of members contained in different Pascal records (that were defined with the any type name). Adapted from Anquetil and Lethbridge. ${ }^{[7]}$

    |  | Member Types the Same | Member Types Different | Total |
    | :--- | ---: | ---: | ---: |
    | Member names the same | $7,709(33.7 \%)$ | $15,174(66.3 \%)$ | 22,883 |
    | Member names different | $158,828(0.2 \%)$ | $66,652,062(99.8 \%)$ | $66,710,890$ |

    There are three storage durations: static, automatic, and allocated.

    ## Usage

    In the translated form of this book's benchmark programs $37 \%$ of defined objects had static storage duration and $63 \%$ had automatic storage duration (objects with allocated storage duration were not included in this count).
    

    0xFFFFFFFF
    

    Figure 449.1: The location of the stack invariably depends on the effect of a processor's pop/push instructions (if they exist). The heap usually goes at the opposite end of available storage. The program image may, or may not, exist in the same address space.

    Table 449.1: Total number of objects allocated (in thousands), the total amount of storage they occupy (in thousands of bytes), their average size (in bytes) and the high water mark of these values (also in thousands). Adapted from Detlefs, Dosser and Zorn. ${ }^{[54]}$

    | Program | Total Objects | Total Bytes | Average Size | Maximum Objects | Maximum Bytes |
    | :--- | ---: | ---: | ---: | ---: | ---: |
    | sis | 63,395 | $15,797,173$ | 249.2 | 48.5 | $1,932.2$ |
    | perl | 1,604 | 34,089 | 21.3 | 2.3 | 116.4 |
    | xfig | 25 | 1,852 | 72.7 | 19.8 | $1,129.3$ |
    | ghost | 924 | 89,782 | 97.2 | 26.5 | $2,129.0$ |
    | make | 23 | 539 | 23.0 | 10.4 | 208.1 |
    | espresso | 1,675 | 107,062 | 63.9 | 4.4 | 280.1 |
    | ptc | 103 | 2,386 | 23.2 | 102.7 | $2,385.8$ |
    | gawk | 1,704 | 67,559 | 39.6 | 1.6 | 41.0 |
    | cfrac | 522 | 8001 | 15.3 | 1.5 | 21.4 |

    455 An object whose identifier is declared with external or internal linkage, or with the storage-class specifier static has static storage duration.

    ## Usage

    In the visible form of the .c files approximately $5 \%$ of occurrences of the keyword static occurred in block scope.

    462 If an initialization is specified for the object, it is performed each time the declaration is reached in the execution of the block;

    ## Usage

    Usage information on initializers is given elsewhere.

    464 For such an object that does have a variable length array type, its lifetime extends from the declaration of the object until execution of the program leaves the scope of the declaration. ${ }^{27)}$

    479 If any other character is stored in a char object, the resulting value is implementation-defined but shall be within the range of values that can be represented in that type.

    ## Usage

    In the visible form of the .c files $2.1 \%$ (.h $2.9 \%$ ) of characters in character constants are not in the basic execution character set (assuming the Ascii character set representation is used for escape sequences).
    

    Figure 464.1: Storage for objects not having VLA type is allocated on block entry, plus storage for a descriptor for each object having VLA type. By the time G has been called, the declaration for a has been reached and storage allocated for it. After G returns, the declaration for $d$ is reached and is storage allocated for $i t$. The descriptor for $d$ needs to include a count of the number of elements in one of the array dimensions. This value is needed for index calculations and is not known at translation time. No such index calculations need to be made for a.

    There are five standard signed integer types, designated as signed char, short int, int, long int, and long long int.

    ## Usage

    It is possible to specify many of the integer types, in C, using more than one sequence of keywords. Usage information on integer types is given elsewhere (see Table 1378.1).

    For each of the signed integer types, there is a corresponding (but different) unsigned integer type (designated with the keyword unsigned) that uses the same amount of storage (including sign information) and has the same alignment requirements.

    ## Usage

    Usage information on integer type specifiers is given elsewhere (see Table 1378.1, which does not include uses of integer types specified via typedef names).

    Table 486.1: Occurrence of objects having different width integer types (as a percentage of all integer types) for embedded source and the SPECint 95 benchmark (separated by a forward slash, e.g.,embedded/SPECint95). Adapted from Engblom. ${ }^{[61]}$

    |  | 8 bits | 16 bits | 32 bits |
    | ---: | ---: | ---: | ---: |
    | unsigned | $70.8 / 1.3$ | $14.0 / 0.4$ | $2.1 / 44.9$ |
    | signed | $2.7 / 0.0$ | $9.4 / 0.3$ | $1.0 / 53.1$ |

    Table 497.1: Occurrence of floating types in various declaration contexts (as a percentage of all floating types appearing in all of these contexts). Based on the translated form of this book's benchmark programs.

    | Type | Block Scope | Parameter | File Scope | typedef | Member | Total |
    | :--- | ---: | ---: | ---: | ---: | ---: | ---: |
    | float | 35.2 | 15.1 | 8.3 | 0.7 | 21.0 | 80.3 |
    | double | 8.5 | 7.9 | 0.5 | 0.7 | 2.2 | 19.7 |
    | long double | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 |
    | Total | 43.6 | 22.9 | 8.8 | 1.5 | 23.2 |  |

    515 The three types char, signed char, and unsigned char are collectively called the character types.
    Table 515.1: Occurrence of character types in various declaration contexts (as a percentage of all character types appearing in all of these contexts). Based on the translated form of this book's benchmark programs.

    | Type | Block Scope | Parameter | File Scope | typedef | Member | Total |
    | :--- | ---: | ---: | ---: | ---: | ---: | ---: |
    | char | 16.4 | 3.6 | 1.2 | 0.1 | 6.6 | 28.0 |
    | signed char | 0.2 | 0.3 | 0.0 | 0.1 | 0.3 | 1.0 |
    | unsigned char | 18.1 | 10.6 | 0.4 | 0.8 | 41.2 | 71.1 |
    | Total | 34.7 | 14.6 | 1.5 | 1.0 | 48.2 |  |

    517 An enumeration comprises a set of named integer constant values.

    ## Usage

    enumeration set of named constants

    A study by Gravley and Lakhotia ${ }^{[74]}$ looked at ways of automatically deducing which identifiers, defined as object-like macros denoting an integer constant, could be members of the same enumerated type. The heuristics used to group identifiers were based either on visual clues (block of \#defines bracketed by comments or blank lines), or the value of the macro body (consecutive values in increasing or decreasing numeric sequence; bit sequences were not considered).
    The 75 header files analyzed contained 1,225 macro definitions, of which 533 had integer constant bodies. The heuristics using visual clues managed to find around 55 groups (average size 8.9 members) having more than one member, the value based heuristic found 60 such groups (average size 6.7 members).

    519 The type char, the signed and unsigned integer types, and the enumerated types are collectively called integer types.

    Table 519.1: Occurrence of integer types in various declaration contexts (as a percentage of those all integer types appearing in all of these contexts). Based on the translated form of this book's benchmark programs.

    | Type | Block Scope | Parameter | File Scope | typedef | Member | Total |
    | :--- | ---: | ---: | ---: | ---: | ---: | ---: |
    | char | 1.8 | 0.4 | 0.1 | 0.0 | 0.7 | 3.1 |
    | signed char | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.1 |
    | unsigned char | 2.0 | 1.2 | 0.0 | 0.1 | 4.6 | 7.9 |
    | short | 0.7 | 0.3 | 0.0 | 0.0 | 0.4 | 1.4 |
    | unsigned short | 2.3 | 0.8 | 0.1 | 0.1 | 3.2 | 6.5 |
    | int | 28.4 | 10.6 | 4.2 | 0.1 | 6.4 | 49.7 |
    | unsigned int | 5.6 | 3.6 | 0.3 | 0.1 | 4.2 | 13.8 |
    | long | 3.0 | 1.2 | 0.1 | 0.1 | 0.8 | 5.1 |
    | unsigned long | 4.8 | 1.9 | 0.2 | 0.1 | 2.1 | 9.1 |
    | enum | 0.9 | 0.9 | 0.4 | 0.4 | 0.8 | 3.3 |
    | Total | 49.6 | 20.8 | 5.4 | 0.9 | 23.2 |  |

    520 The integer and real floating types are collectively called real types.
    

    Figure 519.1: The integer types.
    

    Figure 520.1: The real types.
    arithmetic type
    Integer and floating types are collectively called arithmetic types.
    void
    is incomplete type

    The void type comprises an empty set of values;

    ## Usage

    Information on keyword usage is given elsewhere (see Table 539.1, Table 758.1, Table 788.1, Table 1003.1, Table 1005.1, and Table 1134.1).
    

    Figure 521.1: The arithmetic types.

    Table 525.1: Occurrence of derived types in various declaration contexts (as a percentage of all derived types appearing in all of these contexts, e.g., int $* * a p$ [2] is counted as two pointer types and one array type). Based on the translated form of this book's benchmark programs.

    | Type | Block Scope | Parameter | File Scope | typedef | Member | Total |
    | :--- | ---: | ---: | ---: | ---: | ---: | ---: |
    | $*$ | 30.4 | 37.6 | 3.1 | 0.8 | 5.6 | 77.5 |
    | array | 3.3 | 0.0 | 4.4 | 0.0 | 3.0 | 10.8 |
    | struct | 3.7 | 0.1 | 2.4 | 2.3 | 2.6 | 11.2 |
    | union | 0.2 | 0.0 | 0.0 | 0.1 | 0.2 | 0.5 |
    | Total | 37.7 | 37.8 | 10.0 | 3.3 | 11.3 |  |

    527 Array types are characterized by their element type and by the number of elements in the array.
    Table 527.1: Occurrence of arrays declared to have the given element type (as a percentage of all objects declared to have an array type). Based on the translated form of this book's benchmark programs.

    | Element Type | \% | Element Type | $\%$ |
    | :--- | ---: | :--- | ---: |
    | char | 17.2 | struct * | 3.7 |
    | struct | 16.6 | unsigned int | 2.7 |
    | float | 14.6 | enum | 2.5 |
    | other-types | 10.4 | unsigned short | 2.0 |
    | int | 8.5 | float [] | 1.9 |
    | const char | 8.0 | const char * const | 1.3 |
    | char * | 5.1 | short | 1.1 |
    | unsigned char | 4.4 |  |  |

    530- A structure type describes a sequentially allocated nonempty set of member objects (and, in certain circumstances, an incomplete array), each of which has an optionally specified name and possibly distinct type.
    structure type sequentially allocated objects

    ## Usage

    Usage information on the number of members in structure and union types and their types is given elsewhere.

    ## 533 A function type is characterized by its return type and the number and types of its parameters.

    

    Figure 527.1: Number of arrays defined to have a given number of elements. Based on the translated form of this book's benchmark programs.
    
    a
    
    b

    Figure 530.1: Three examples of possible member clusterings. In (a) there are two independent groupings, (b) shows a hierarchy of groupings, while in (c) it is not possible to define two C structure types that share a subset of common member (some other languages do support this functionality). The member c, for instance, might be implemented as a pointer to the value, or it may simply be duplicated in two structure types.

    ## Usage

    Usage information on function return types is given elsewhere (see Table 1005.1) as is information on parameters (see Table 1831.1).

    ## - A pointer type may be derived from a function type, an object type, or an incomplete type, called the referenced type.

    Table 539.1: Occurrence of objects declared using a given pointer type (as a percentage of all objects declared to have a pointer type). Based on the translated form of this book's benchmark programs.

    | Pointed-to Type | $\%$ | Pointed-to Type | $\%$ |
    | :--- | ---: | :--- | ---: |
    | struct | 66.5 | struct $\%$ | 1.8 |
    | char | 8.0 | int | 1.8 |
    | union | 6.0 | const char | 1.3 |
    | other-types | 5.5 | char $*$ | 1.2 |
    | void | 3.3 | str \| str |  |
    | unsigned char | 2.6 | _double \| _double |  |
    | unsigned int | 2.2 | _double \| _double |  |

    unqualified type Any type so far mentioned is an unqualified type.

    Table 554.1: Occurrence of qualified types as a percentage of all (i.e., qualified and unqualified) occurrences of that kind of type (e.g., * denotes any pointer type, struct any structure type, and array of an array of some type). Based on the translated form of this book's benchmark programs.

    | Type Combination | $\%$ | Type Combination | $\%$ |
    | :--- | ---: | :--- | ---: |
    | array of const | 26.7 | const $*$ | 0.4 |
    | const integer-type | 4.8 | const union | 0.3 |
    | const real-type | 2.7 | volatile struct | 0.1 |
    | * const | 2.6 | volatile integer-type | 0.1 |
    | const struct | 2.4 | *volatile | 0.1 |

    Each unqualified type has several qualified versions of its type, ${ }^{38)}$ corresponding to the combinations of one, 555 two, or all three of the const, volatile, and restrict qualifiers.

    Table 555.1: Occurrence of type qualifiers on the outermost type of declarations occurring in various contexts (as a percentage of all type qualifiers on the outermost type in these declarations). Based on the translated form of this book's benchmark programs.

    | Type Qualifier | Local | Parameter | File Scope | typedef | Member | Total |
    | :--- | ---: | ---: | ---: | ---: | ---: | ---: |
    | const | 18.5 | 4.3 | 50.8 | 0.0 | 1.2 | 74.8 |
    | volatile | 1.6 | 0.1 | 3.0 | 0.1 | 20.4 | 25.2 |
    | volatile const | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 |
    | Total | 20.1 | 4.4 | 53.8 | 0.1 | 21.6 |  |

    559 Similarly, pointers to qualified or unqualified versions of compatible types shall have the same representation and alignment requirements.

    570 Except for bit-fields, objects are composed of contiguous sequences of one or more bytes, the number, order, and encoding of which are either explicitly specified or implementation-defined.
    pointer
    to qualified/unqualified types
    

    Figure 559.1: Data storage organization for the PIC18CXX2 devices ${ }^{[121]}$ The 4,096 bytes of storage can be treated as a linear array or as 16 banks of 256 bytes (different instructions and performance penalties are involved). Some storage locations hold Special Function Registers (SFR) or General Purpose Registers (GPR). Free denotes storage that does not have a preassigned usage and is available for general program use.
    

    Figure 570.1: Developers who use little-endian often represent increasing storage locations going down the page. Developers who use big-endian often represent increasing storage locations going up the page. The value returned by an access to storage location 0 , using a pointer type that causes 16 bits to be read, will depend on the endianness of the processor.

    Table 570.1: Byte order (indicated by the value of the digits) used by various processors for some integer and floating types, in different processor address spaces (all address spaces if none is specified).

    | Vendor | 16-bit integer | 32-bit integer | 64-bit integer | 32-bit float | 64-bit float |

    If there are $N$ value bits, each bit shall represent a different power of 2 between 1 and $2^{N-1}$, so that objects of that type shall be capable of representing values from 0 to $2^{\mathrm{N}}-1$ using a pure binary representation;

    Table 594.1: Pattern of bits used to represent decimal numbers using various coding schemes.

    | Decimal | Binary | Gray code | 111 biased | 2-out-of-5 |
    | :--- | :--- | :--- | :--- | :--- |
    | 0 | 0000 | 0000 | 0111 | 00011 |

    sign bit representation matically

    If the sign bit is one, the value shall be modified in one of the following ways:

    Several operators convert operand values from one type to another automatically.
    

    Figure 570.2: The Unisys A Series ${ }^{[171]}$ uses the same representation for integer and floating-point types. For integer values bit 47 is unused, bit 46 represents the sign of the significand, bits 45 through 39 are zero, and bits 38 through 0 denote the value (a sign and magnitude representation). For floating values bit 47 represents the sign of the exponent and bits 46 through 39 represent the exponent (the representation for double-precision uses an additional word with bits 47 through 39 representing higher order-bits of the exponent and bits 38 through 0 representing the fractional portion of the significand).
    

    Figure 610.1: Decimal values obtained by interpreting a sequence of bits in various ways. From the inside out: unsigned, binary, two's complement, sign and magnitude, and one's complement.

    ## Usage

    Usage information on the cast operator is given elsewhere (see Table 1134.1).
    Table 653.1: Occurrence of implicit conversions (as a percentage of all implicit conversions; an _ prefix indicates a literal operand). Based on the translated form of this book's benchmark programs.

    | Converted to | Converted from | \% | Converted to | Converted from | \% |
    | :---: | :---: | :---: | :---: | :---: | :---: |
    | ( unsigned char) | int | 33.0 | ( int) | unsigned short | 1.9 |
    | ( unsigned short) | int | 17.7 | (unsigned long) | int | 1.8 |
    | ( other-types) | other-types | 11.3 | ( unsigned int) | int | 1.7 |

    | ( int ) | unsigned char | 2.3 |  |  |  |

    ## 675 These are called the integer promotions. ${ }^{48)}$

    Table 675.1: Occurrence of integer promotions (as a percentage of all operands appearing in all expressions). Based on the translated form of this book's benchmark programs.

    | Original Type | $\%$ | Original Type | $\%$ |
    | :--- | :--- | :--- | :---: |
    | unsigned char | 2.3 | char | 1.2 |
    | unsigned short | 1.9 | short | 0.5 |

    687 If the value of the integral part cannot be represented by the integer type, the behavior is undefined. ${ }^{50)}$
    710 Otherwise, the integer promotions are performed on both operands.

    Usage information on integer promotions is given elsewhere (see Table 675.1).
    

    Figure 687.1: Illustration of the effect of integer addition wrapping rather than saturating. A value has been added to all of the pixels in the left image to increase the brightness, creating the image on the right. With permission from Jordán and Lotufo. ${ }^{[89]}$
    arithmetic conversions integer types

    ## Ivalue

    converted to valueThen the following rules are applied to the promoted operands:

    ## Usage

    Usage information on implicit conversions is given elsewhere (see Table 653.1).

    Except when it is the operand of the sizeof operator, the unary \& operator, the ++ operator, the -- operator, 725 or the left operand of the . operator or an assignment operator, an lvalue that does not have array type is converted to the value stored in the designated object (and is no longer an Ivalue).

    ## Usage

    Usage information on the number of translation time references, in the source code, is given elsewhere (see Figure 1821.5, Figure 1821.6).

    Any pointer type may be converted to an integer type.

    ## Usage

    Usage information on pointer conversions is given elsewhere (see Table 758.1 and Figure 1134.1).

    ## pointer

    converted to pointer to different object or typeA pointer to an object or incomplete type may be converted to a pointer to a different object or incomplete type. 758
    

    Figure 725.1: Execution-time counts of the number of reads and writes of the same object (declared in block or file scope, i.e., not allocated storage) for a subset of the MediaBench benchmarks; items above the diagonal indicate more writes than reads. Data kindly supplied by Caspi, based on his research. ${ }^{[31]}$

    Table 758.1: Occurrence of implicit conversions that involve pointer types (as a percentage of all implicit conversions that involve pointer types). Based on the translated form of this book's benchmark programs.

    | To Type | From Type | \% | To Type | From Type | \% |
    | :---: | :---: | :---: | :---: | :---: | :---: |

    Figure 770.15: The ambiguity of patterns defined by the first and last letter and an interior letter pair, as a function of the position of the first letter of the pair. Plots are for different word lengths using the 65,000 words from CLAWS ${ }^{[107]}$ (as used by the aspell tool). The fixation position is taken to be midway between the interior letter pair.
    

    Figure 770.16: The ambiguity of source code identifiers, which can include digits as well as alphabetic characters. Plots are for different identifier lengths. A total of 344,000 identifiers from the visible form of the .c files were used.

    ## Usage

    Table 770.3 shows the relative frequency of the different kinds of tokens in a source file (actual token count information is given elsewhere). Adding the percentages for Preceded by Space and First on Line (or followed by space and last on line) does not yield $100 \%$ because of other characters occurring in those positions. Some tokens occur frequently, but contribute a small percentage of the characters in the visible source (e.g., punctuators). Identifier tokens contribute more than $40 \%$ of the characters in the .c files, but only represent $28.5 \%$ of the tokens in those files.

    Table 770.3: Occurrence of kinds of tokens in the visible form of the .c and .h files as a percentage of all tokens (value in parenthesis is the percentage of all non-white-space characters contained in those tokens), percentage occurrence (for .c files only) of token kind where it was preceded/followed by a space character, or starts/finishes a visible line. While comments are not tokens they are the only other construct that can contain non-white-space characters. While the start of a preprocessing directive contains two tokens, these are generally treated by developers as a single entity.

    | Token | \% of Tokens <br> in .c files | \% of Tokens <br> in .h files | \% Preceded <br> by Space | \% Followed <br> by Space | \% First Token <br> on Line | \% Last Token <br> on Line |
    | :--- | :---: | :--- | :--- | :--- | :--- | :--- | ---: |
    | punctuator | $53.5(11.4)$ | $48.1(77.5)$ | 27.5 | 29.7 | 3.7 | 25.3 |
    | identifier | $29.8(43.4)$ | $20.8(30.6)$ | 54.9 | 27.6 | 1.4 | 1.2 |
    | constant | $6.9(3.8)$ | $21.6(15.3)$ | 70.3 | 4.4 | 0.1 | 1.6 |
    | keyword | $6.9(5.8)$ | $5.4(4.2)$ | 79.9 | 82.5 | 10.3 | 3.6 |
    | comment | $1.9(31.0)$ | $3.4(40.3)$ | 53.4 | 2.2 | 41.2 | 97.4 |
    | string-literal | $1.0(4.6)$ | $0.8(2.2)$ | 59.9 | 5.7 | 0.7 | 8.0 |
    | pp-directive | $0.9(1.1)$ | $4.9(4.4)$ | 4.7 | 78.4 | 0.0 | 18.2 |
    | header-name | $0.0(0.0)$ | $0.0(0.0)$ | - | - | - | - |

    ## preprocessing tokens white space separation

    Preprocessing tokens can be separated by white space;

    ## Usage

    Table 770.3 shows the relative frequency of white space occurring before and after various kinds of tokens.
    keyword: one of

    | auto | enum | restrict | unsigned |
    | :--- | :--- | :--- | :--- |
    | break | extern | return | void |
    | case | float | short | volatile |
    | char | for | signed | while |
    | const | goto | sizeof | _Bool |
    | continue | if | static | _Complex |

    | Future | will write will walk | will have written will have walked | will be writing will be walking | will have been writing will have been walking |

    

    Figure 792.10: Number of identifiers containing a given number of components. In the left graph a component is defined as a character sequence delimited by one or more underscore characters, _, the start of the identifier, or its ending, e.g., the identifier big_blk_proboscis is considered to contain three components, one of which is a word. In the right graph a component is any sequence of lower-case letters, a sequence of two or more upper-case characters (i.e., the sequence is terminated by one or more digit characters or a letter having opposite case), or an upper-case character followed by a sequence of lower-case letters (this form of identifier might be said to be written in camelCase). For instance, the identifier bigBlk4proboscis is considered to contain three components, one of which is a word. A word is defined by the contents of the ispell 65,000 word list (this means, for instance, that the character sequence proboscis is not considered to be a word). Based on the visible form of the .c files.

    Table 792.9: Probability of an adjective occurring at a particular position relative to other adjectives. Adapted from CelceMurcia. ${ }^{[34]}$

    | determiner | option | size | shape | condition | age | color | origin | noun |

    ## Usage

    integer constant usage

    Having some forms of constant tokens (also see Figure 842.1) follow Benford's law ${ }^{[82]}$ would not be surprising because the significant digits of a set of values created by randomly sampling from a variety of different distributions converges to a logarithmic distribution (i.e., Benford's law). ${ }^{[81]}$ While the results for decimal-constant (see Figure 825.2) may appear to be a reasonable fit, applying a chi-squared test shows the fit to be remarkably poor ( $\chi^{2}=132,398$ ). The first nonzero digit of hexadecimal-constants appears to be approximately evenly distributed.
    

    Figure 825.1: Number of integer constants having the lexical form of a decimal-constant (the literal 0 is also included in this set) and hexadecimal-constant that have a given value. Based on the visible form of the . c and . h files.
    

    Figure 825.2: Probability of a decimal-constant or hexadecimal-constant starting with a particular digit; based on .c files. Dotted lines are the probabilities predicted by Benford's law (for values expressed in base 10 and base 16), i.e., $\log \left(1+d^{-1}\right)$, where $d$ is the numeric value of the digit.

    Table 825.1: Occurrence of various kinds of integer-constants (as a percentage of all integer constants; note that zero is included in the decimal-constant count rather than the octal-constant count). Based on the visible form of the .c and .h files.

    884 The value of an integer character constant containing a single character that maps to a single-byte execution character is the numerical value of the representation of the mapped character interpreted as an integer.

    Table 884.1: Occurrence of a character-constant appearing as one of the operands of various kinds of binary operators (as a percentage of all such constants; includes escape sequences). Based on the visible form of the .c files. See Table 866.3 for more detailed information.

    | Operator | $\%$ |
    | :--- | ---: |
    | Arithmetic operators | 4.5 |
    | Bit operators | 0.5 |
    | Equality operators | 31.3 |
    | Relational operators | 4.1 |

    885 The value of an integer character constant containing more than one character (e.g., 'ab'), or containing a character or escape sequence that does not map to a single-byte execution character, is implementationdefined.

    Table 885.1: Number of character-constants containing a given number of characters. Based on the visible form of the .c files.

    | Number of Characters | Occurrences | Number of Characters | Occurrences |
    | :---: | ---: | :---: | ---: |
    | 0 | 27 | 4 | 21 |
    | 1 | 50,590 | 5 | 4 |
    | 2 | 0 | 6 | 4 |
    | 3 | 8 | 7 | 0 |

    string literal syntax

    ```
    string-literal:
    " s-char-sequence}\mp@subsup{}{opt}{}
    L" s-char-sequence```
